

## **Use of PandaPower for Load Flow Analysis**

## Introduction

For the comparison, we have used WSCC 9 bus system. In the simulations, we tried to simulate the IEEE 14 bus system, but there were mismatches with the pandapower simulation and the PSSE simulation output.

WSCC 9 bus system consists of 9 buses ( six 230kV, 16.5kV, 13.8kV, and 18kV), 3 generators ( 450MW max, 240MW max and 90MW max), 3 loads, 3 transformers and 6 transmission lines.

This system was simulated in panda power according to the data provided for the assignment. Then the data from the simulations were cross checked with the PSSE simulations and the panda power system was validated accordingly.

Output simple plot from panda power. This diagram is used in future contingency analysis.

**Perform the load flow analysis of a test power system using Pandapower in the base case scenario.**

## Contingency analysis

We have tested the system with N-1 contingency analysis.

### Loss of transmission line

For ease, we have included only 2 transmission line contingencies. All the output transmission line data in PSSE matches with the output in the panda power.

### Contingency 1 - Loss of transmission line 1

Output from the simulation in Panda Power

Critical Elements after Removing Line 1

In this simple plot, the transformer 1, which is connected to the bus 2 is marked in red since it is overloaded. Voltage at the bus 5 has gone under 0.95pu, so that it is marked in red. Since the terminal voltage of the transmission line connected to the bus 5 also goes down it is marked in red.

1.012016	-11.6221	1.012016	-11.622105
1.01351	-14.99047	1.013150	-14.990467
1.0069	-15.63357	1.006937	-15.633577
1.0278	-11.28	1.027817	-11.283380

When the transformer is switched off, the link between the bus where the generator is connected and the grid is interrupted. So that in PSSE it gives an error since the generator operates in the islanded mode To overcome that, we need to turn off the bus bar in which the generator is connected. That's why we get NaN values for bus results in this contingency.

```

*Output from the simulation in Panda Power*

Critical Elements after Removing Transformer 3

*Output from the simple plot in Panda Power*

*PSSE output*

## **Discussion**

- WSCC 9 bus system which was used to compare the results in the base case scenario and for the panda power simulation and PSSE simulation. The results which were obtained from the both methods are equal.
- In the panda power, when calculating the loading percentage of transformers, they have used the MVA base defined for the system as the base MVA. So that some transformers are seen as overloaded.
- For the lines, panda power has calculated the rated MVA rating of the transmission line using the operating voltage and the rated current.
